

Towards the Simulation of Bulk Properties via Molecular Dynamics

MAIREAD HEIGER, DR. JEREMY SCHMIT

KANSAS STATE UNIVERSITY

Biomolecular Simulations under Realistic Macroscopic Salt Conditions

Gregory A. Ross, Ariën S. Rustenburg, Patrick B. Grinaway, Josh Fass, John D. Chodera

- Conformations, functions, binding of biomolecules are sensitive to ion content
 - Relevant to pharmacological design
- Simulations fix salt content and so may not accurately represent actual local environment

Fluctuations in Local Environment

- How do fluctuations affect processes like folding, screening layer interactions, and binding?
- How do fluctuations affect free energy?

■ -- local environment
(simulation volume)

■ -- nonlocal environment
(bulk)

● -- positive ion

● -- negative ion

Single particle model

- One degree of freedom
- Anions and cations fluctuate together
- Simplest but least physical

■ -- local environment
(simulation volume)

● -- salt pair

■ -- nonlocal environment
(bulk)

Salt pair model

- Two degree of freedom
- Anions and cations fluctuate together
- No electrostatic contribution
- Commonly used for computations

■ -- local environment
(simulation volume)

■ -- nonlocal environment
(bulk)

● -- positive ion

● -- negative ion

Independent fluctuations

- Two degree of freedom
- Anions and cations fluctuate independently
- Electrostatic contribution

■ -- local environment
(simulation volume)

■ -- nonlocal environment
(bulk)

● -- positive ion

● -- negative ion

Describing independent fluctuations

Electrostatic
component

Two chemical
components

$$Z = \sum_{N_+, N_-} \frac{V^{N_+}}{N_+!} * \frac{V^{N_-}}{N_-!} * e^{\frac{e^2}{8\pi\epsilon R kT} (Q + N_+ - N_-)^2} * e^{(N_+ + N_-) \frac{\mu}{kT}}$$

Two translational
components

N_{\pm} = number of \pm ions
 V = volume of local environment
 Q = charge of macromolecule
 R = radius of local environment
 μ = chemical potential
 e = charge of electron

Evaluating Free Energy using SLTCAP

$$F(N_+, \delta N_+, N_-, \delta N_-, Q, V, \mu) = -kT \ln Z$$

$$N_{\pm} = V c_0 * e^{\mp \text{arcsinh}\left(\frac{Q}{2 e V c_0}\right)}$$

N_{\pm} = number of \pm ions

δN_{\pm} = number of fluctuations

V = volume of local environment

Q = charge of macromolecule

R = radius of local environment

μ = chemical potential

e = charge of electron

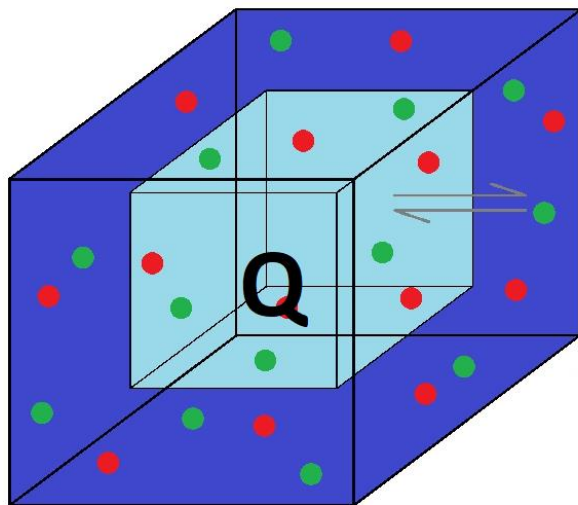

$$F(\delta N_+, \delta N_-, Q, V, c_0)$$

Free Energy [$F(0 e)/kT$]

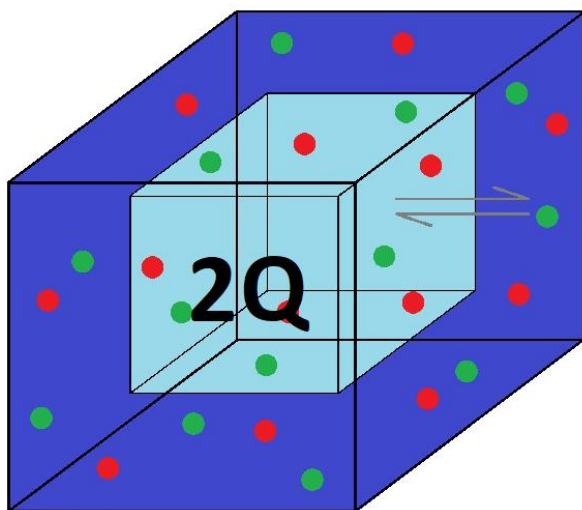

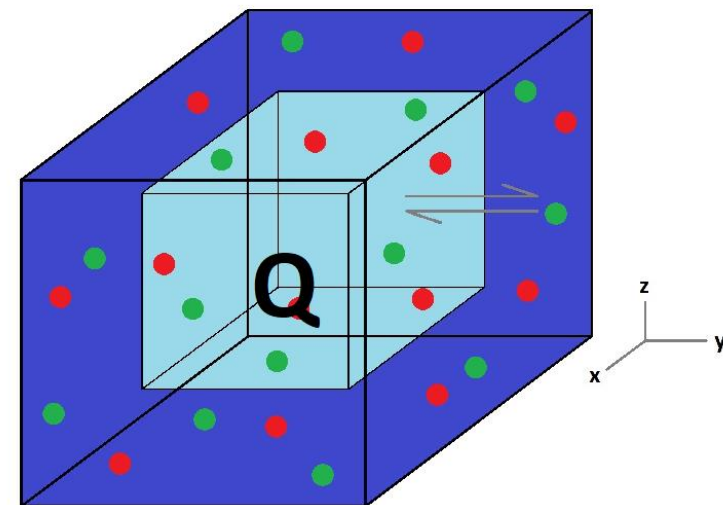

Free Energy [$F(-5 e)/kT$]

+

+

■ -- local environment (simulation volume)

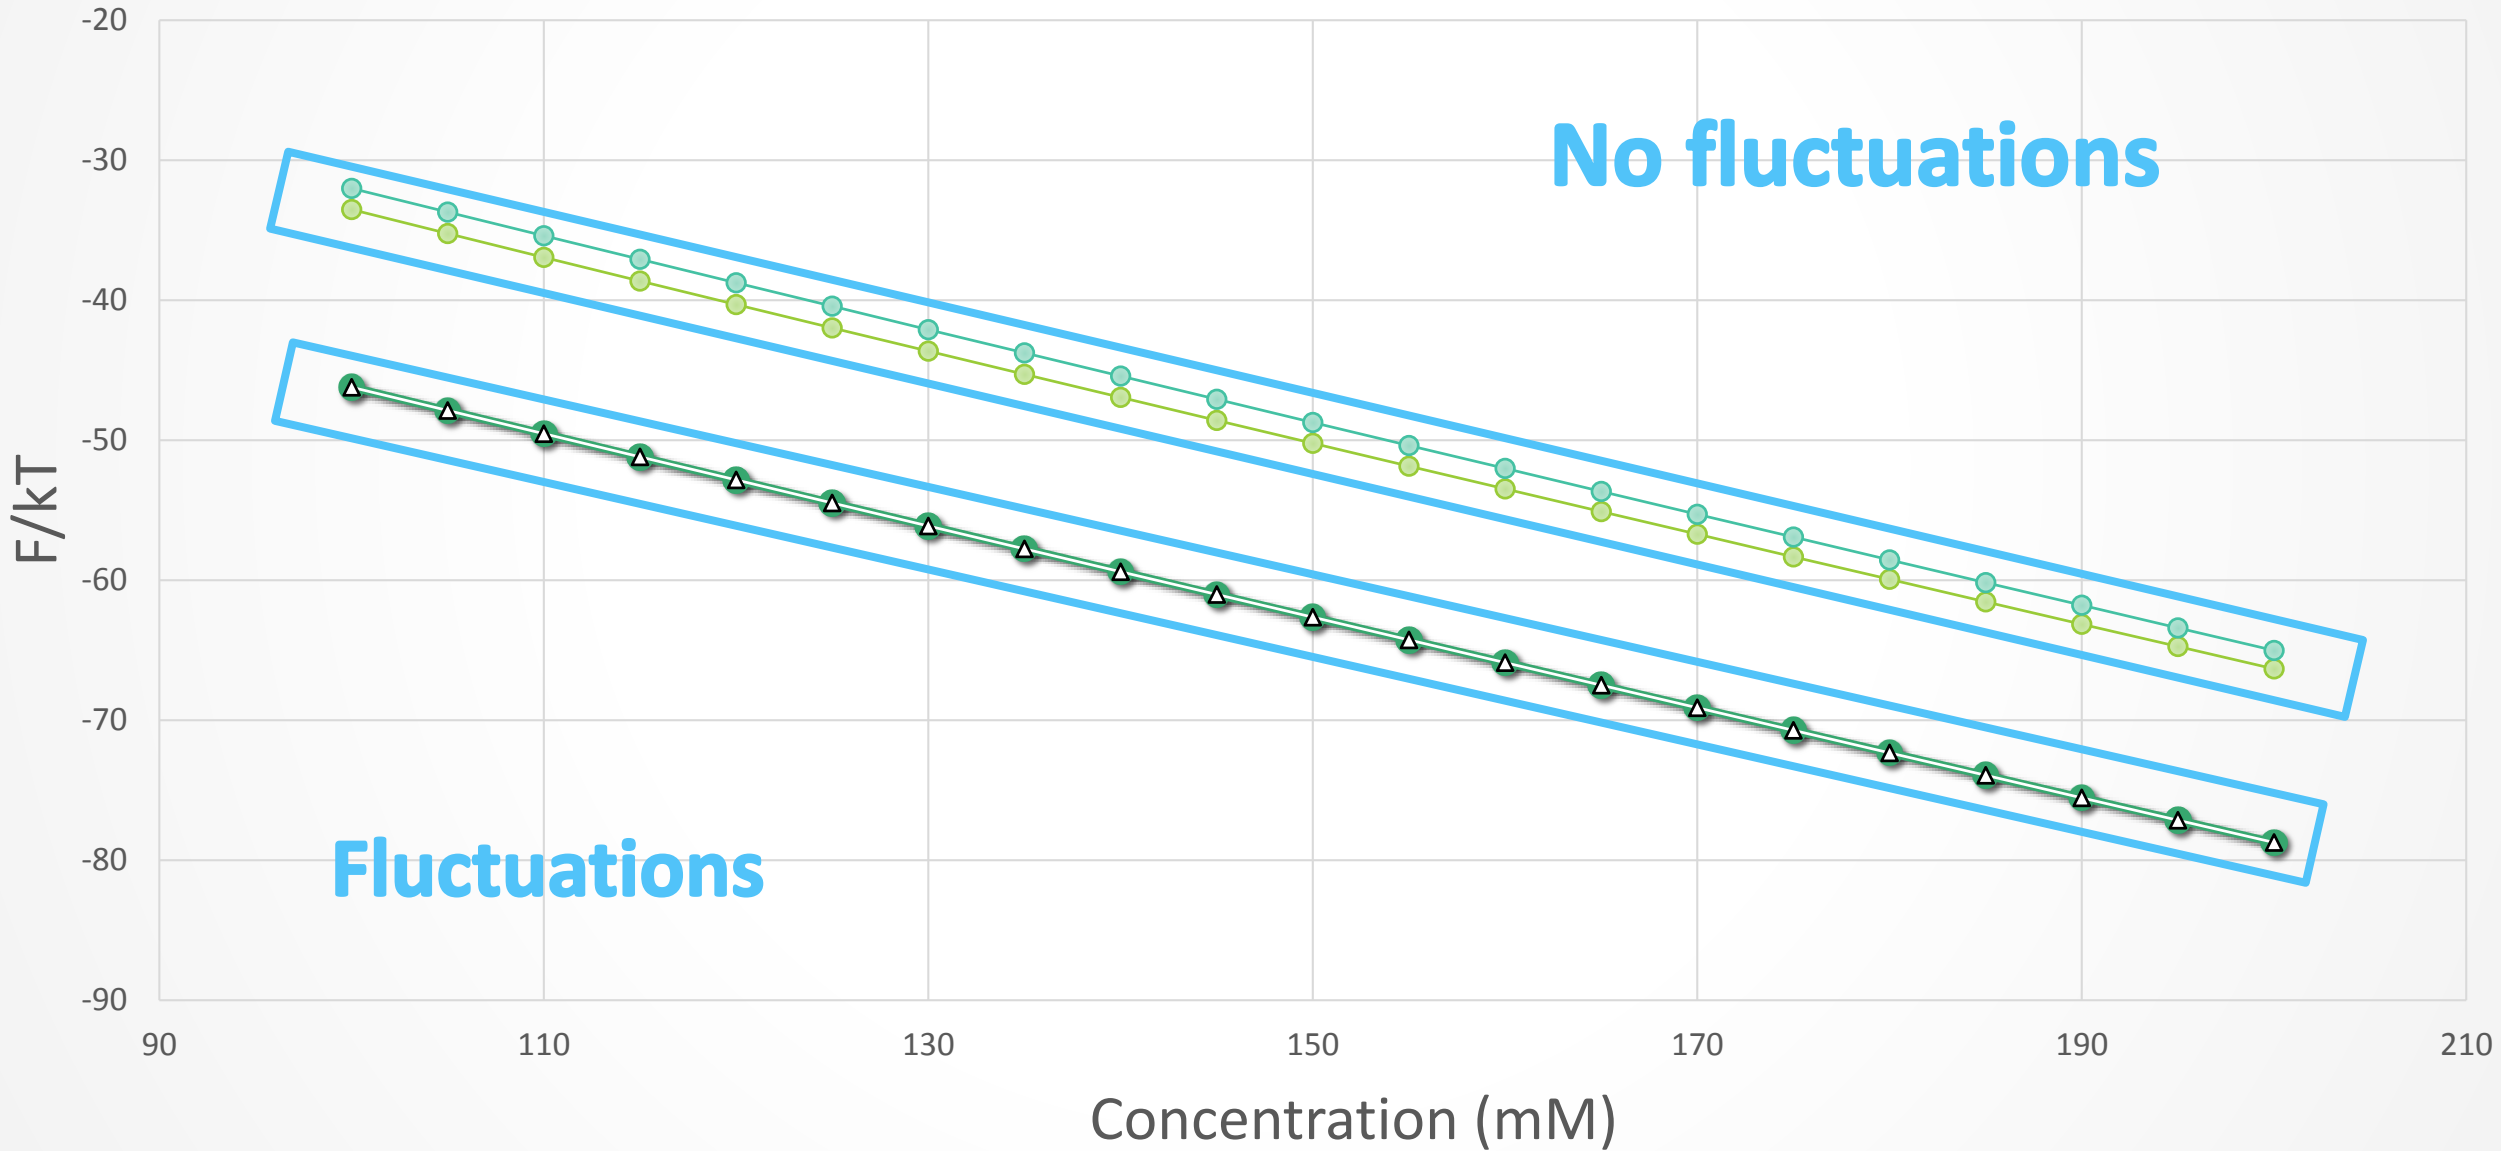

■ -- nonlocal environment (bulk)

● -- positive ion

● -- negative ion

Free Energy

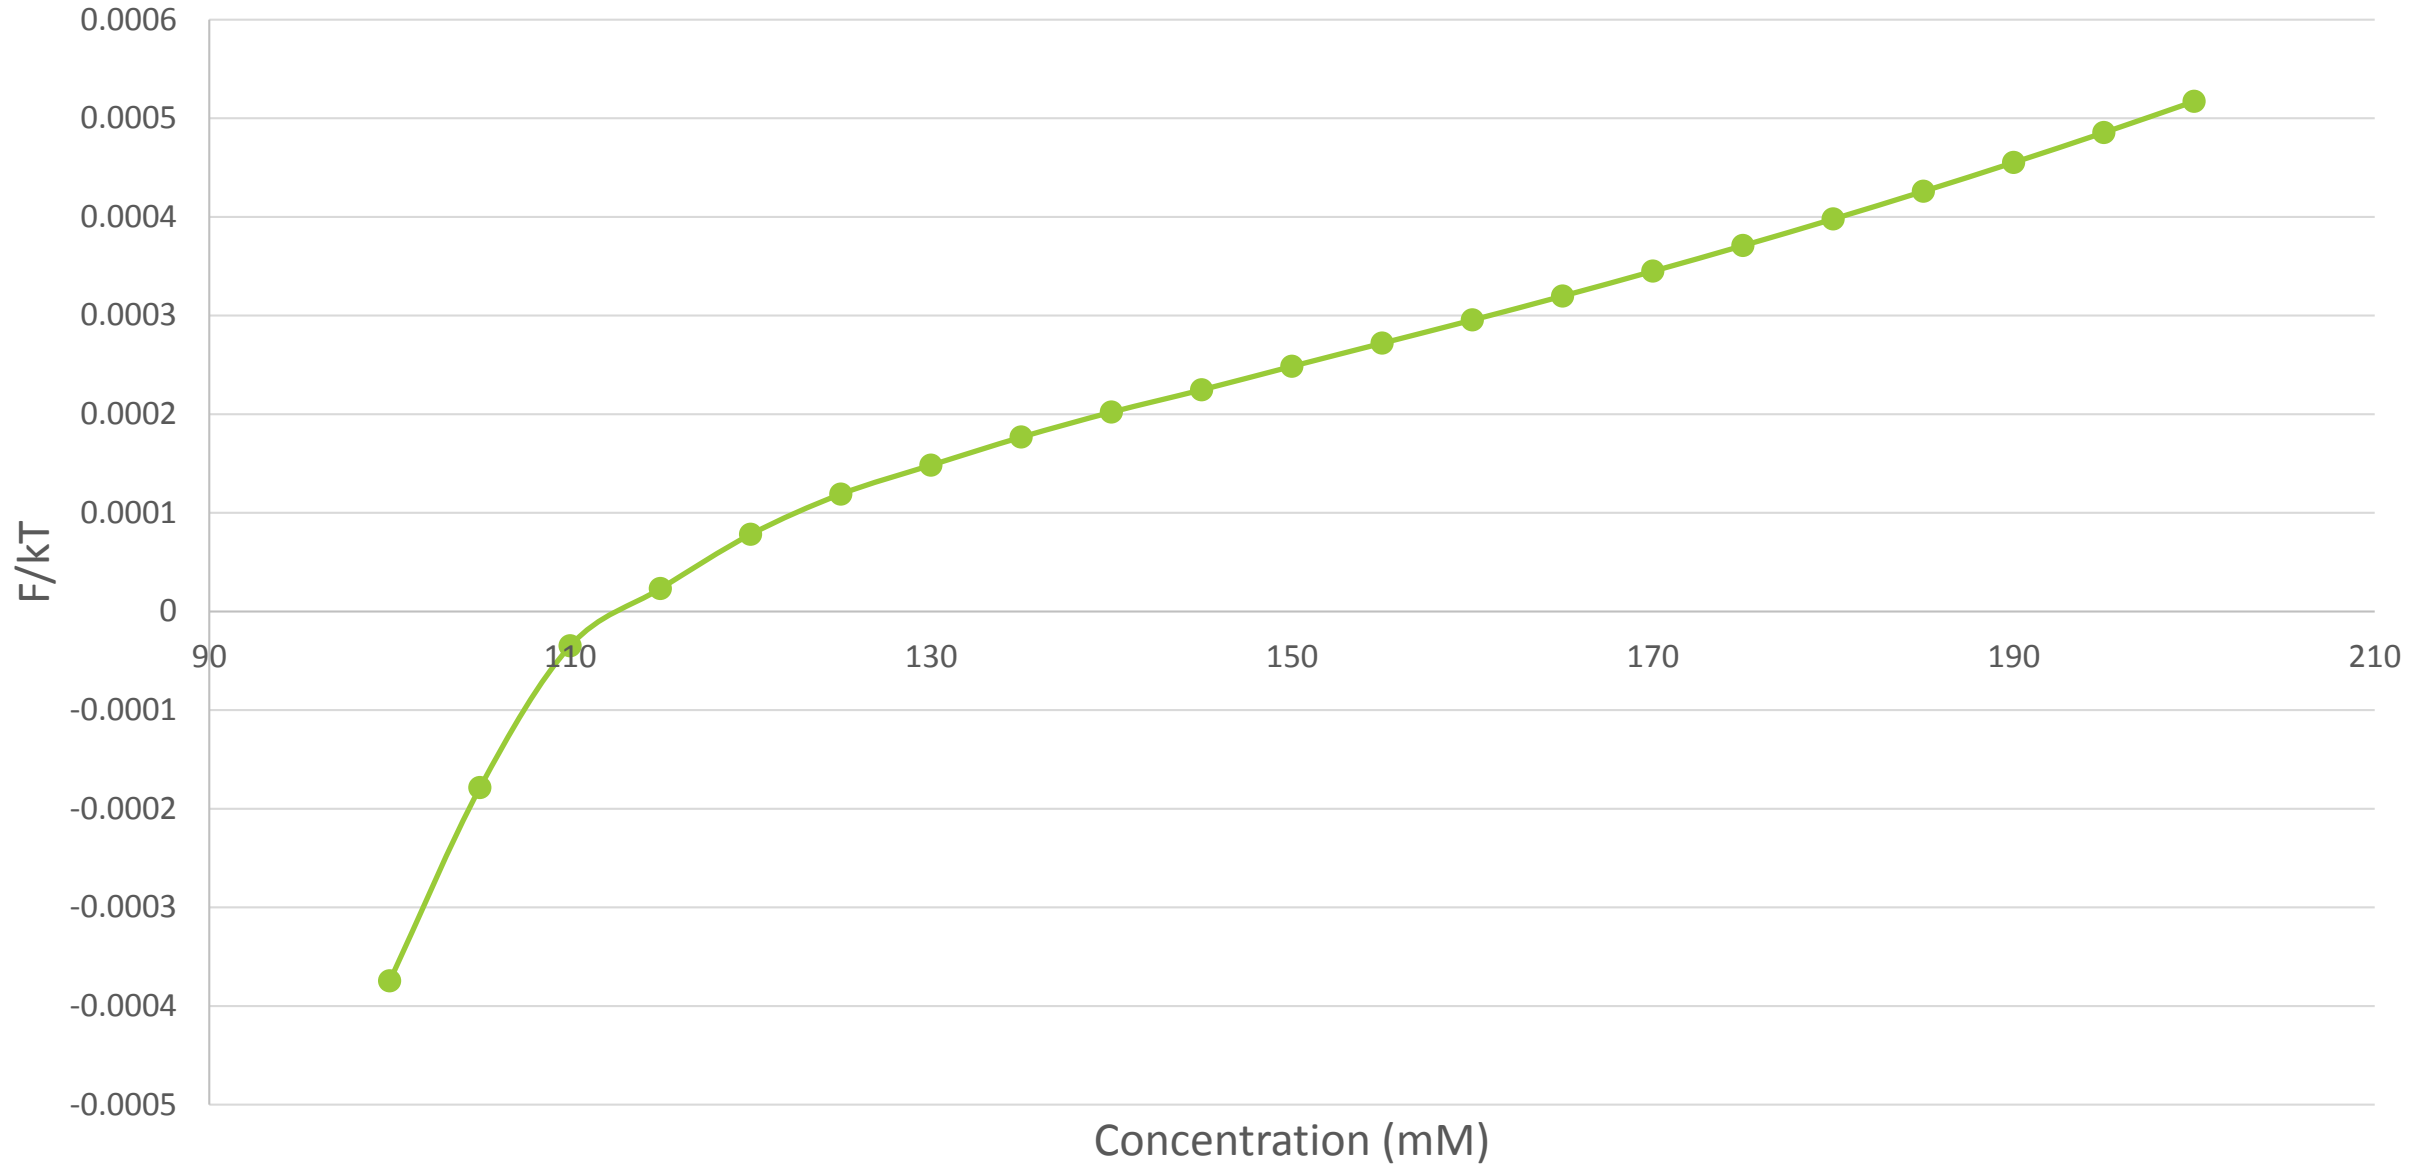

● $2 * F(-10 \text{ e}): \text{fluc}$ ● $2 * F(-10 \text{ e}): \text{no fluc}$ Δ $F(0 \text{ e}): \text{fluc} + F(-20 \text{ e}): \text{fluc}$ ● $F(0 \text{ e}): \text{no fluc} + F(-20 \text{ e}): \text{no fluc}$

$$\Delta F [2F(-10 e) - (F(0 e) + F(-20 e))]$$

ΔF fluctuations

Further Research

Explain why $\Delta F_{fluctuations} \ll \Delta F_{no\ fluctuations}$

Collaborate to implement model in simulations
